

Botrytis control

The growing season has just passed, but preparations are already necessary to regain a good crop in the coming spring. Botrytis control, which will start in late summer, is an important part of that.

It is important to carry out Botrytis control with Collis, amongst other things, after mowing. To kill the wounds on the plant and the spores present on the ground. These spores will eventually become winter spores and they will cause collapsing of stems in the spring.

Therefore, spraying in the fall is just as important as spraying in the spring. And also remove crop residues in connection with a possible Botrytis and nematode infection.

Cutting height of foliage:

Studies have revealed that a Botrytis inhibitory effect arises if the crop is not mown too short in autumn. Thus the risk of collapsing stems in the spring is reduced. Also studies have shown that a cutting height of 7-10 cm above the ground is better for the crop than a cutting height directly above the ground.
